1 Executive Summary

This project focused on building a SQL-driven customer retention intelligence system for a direct-to-consumer fashion retail business. The primary objective was to analyze customer purchasing behavior, promotional dependency, loyalty patterns, and retention drivers in order to support long-term business decision making.

Using Python-based data preprocessing and feature engineering, multiple customer intelligence metrics were created, including loyalty score, promotional dependency score, customer value tier, satisfaction flag, and at-risk customer indicators.

SQL analysis revealed several important business insights:

- High-value customers contributed significantly larger average revenue
- Loyal customers demonstrated low promotional dependency and stronger repeat purchase behavior
- A substantial portion of revenue remained promotion-driven
- Certain regions showed strong spending with relatively lower discount dependency
- Categories such as accessories and footwear demonstrated stronger retention potential

An interactive Power BI dashboard was developed to visualize customer segmentation, geographic opportunities, loyalty behavior, and promotional risk patterns for executive-level decision making.

Based on the findings, a retention playbook was created recommending a gradual transition from aggressive discount-driven growth toward retention-focused and experience-driven customer engagement strategies.

Overall, the project demonstrates how customer intelligence, SQL analytics, and business-focused dashboarding can support sustainable customer retention and long-term profitability optimization.
